

全球市场评论: 伊朗遭袭后对市场的思考 (摘要)

- 伊朗危机对全球经济和宏观市场的主要传导渠道是其对能源市场的影响，其中危机的严重程度和预期持续时间是关键所在。风险溢价上升和分布范围扩大可能是市场的初步反应。近期波动可能延续，而市场在进入周末时已经消化了一定程度的增长下行风险和通胀上行风险。
- 对于股市和债市而言，影响将是负面的，但只有严重且持续的石油市场中断才会对全球增长产生重大影响。我们预计，除非局势迅速得到解决，否则周期性行业和石油进口方可能将面临压力，其中一些行业和市场今年开局强劲，可能因仓位调整而面临冲击。
- 在外汇市场，负面的供应冲击和增长风险最初应会是分配效应的主导因素。在风险偏好下降和油价上涨的环境中，美元和日元可能是避险货币，而在瑞郎大幅升值时瑞士国家银行进行干预的风险使我们对瑞郎持相对谨慎的态度。如果大宗商品的影响持续，那么通过贸易条件产生的分配效应可能会重现，不过与之相制衡的因素是今年以来面临大宗商品利好因素之际一些货币已经表现出色、以及更严重的避险情绪可能削弱大宗商品上行带来的裨益。
- 在利率方面，供应驱动的油价上涨对通胀曲线和名义利率的影响通常较为有限，但可能会令近期美国收益率曲线前端的趋平走势和中段的出色表现得以持续。对于欧元区收益率曲线，我们认为其前端面临一些鹰派风险，曲线面临趋平压力。短期内波动性可能会加大，给互换利差带来风险，如果市场计入冲突持续时间更久的因素，则这一风险可能会加剧。

Market Thoughts Following the Strikes in Iran

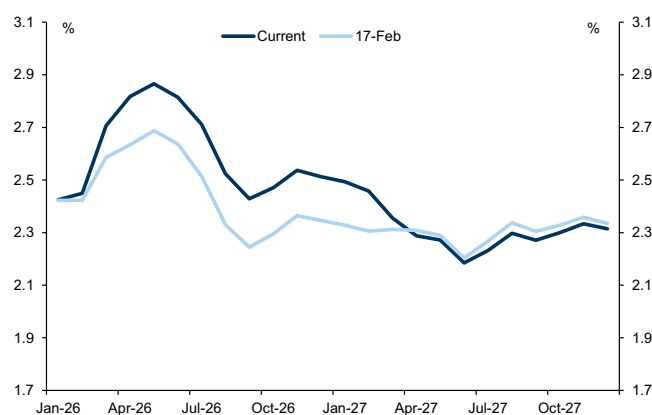

The primary transmission channel of the Iran crisis on the global economy and markets is through its impact on energy markets. The initial market response is generally to raise risk premium on the back of higher uncertainty and wider distributions. Though not necessarily attributable to Iran and/or oil-related concerns, markets have recently incorporated some of the broader risks to the outlook, with growth pricing sitting firmly below our economists' US baseline (图表 1) and near-term inflation fixes moving higher into the weekend (图表 2). But as it is typically hard to sustain broad-based pressure on economies or markets on the basis of uncertainty alone, it is likely that without sustained oil price shifts, the asset impact will begin to “localize,” shifting back towards directly affected assets.

图表 1: Markets have downgraded the US growth outlook recently, with pricing below our economists' baseline

The impact of the energy price shock will depend on a combination of severity and expected longevity. Our commodity team has laid out the [key risk scenarios](#), with the most damaging being a sustained full disruption to oil flows through the Strait of Hormuz. Those disruptions have already begun, but a key question is how long they may plausibly last.

In terms of the cross-asset impact, there are three important channels through which this kind of oil shock typically operates, beyond the initial increase in risk premium:

1. A negative supply shock that increases the risks to growth on aggregate.
2. A distributional shock that reallocates income from oil-consuming sectors and countries to oil-producing sectors and countries.
3. A boost to headline inflation that disproportionately affects EM central banks with higher commodity weights and less anchored inflation expectations.

At a high level, this means that gauging asset market reactions to a sustained oil shock is generally about assessing where different assets lie in terms of these

income shocks (terms of trade shifts) and exposures to the growth and headline inflation shifts.

In equities, the impact of a risk and growth shock is clearly negative, but only a severe and sustained oil price disruption (as in 1990 or 2022, for instance) would have large effects on the global growth picture. Geographically, oil-importers are clearly more exposed (including markets like Korea, Taiwan, Japan, Türkiye and India) and within the major markets the US is generally relatively better placed than many others. Cyclical sectors are likely to see pressure in this scenario, particularly consumer-facing areas, including airlines, and industrial oil users. Energy producers should outperform. Some of these cyclical sectors and markets have had a strong start to the year and might be more vulnerable to position adjustments.

The impact on credit markets is likely to be similar—a net widening of spreads but with a strong distributional tilt, favoring energy producers at the expense of consumers and cyclicals. Within the EM credit universe, even some of the GCC oil exporters are likely to see a widening in spreads similar to October 2023 with weaker sovereigns more reliant on capital inflows among the most vulnerable. We would expect equity volatility to rise and continue to think that long volatility expressions like these, which are highly negatively correlated with equities/credit and quite liquid, are good portfolio additions.

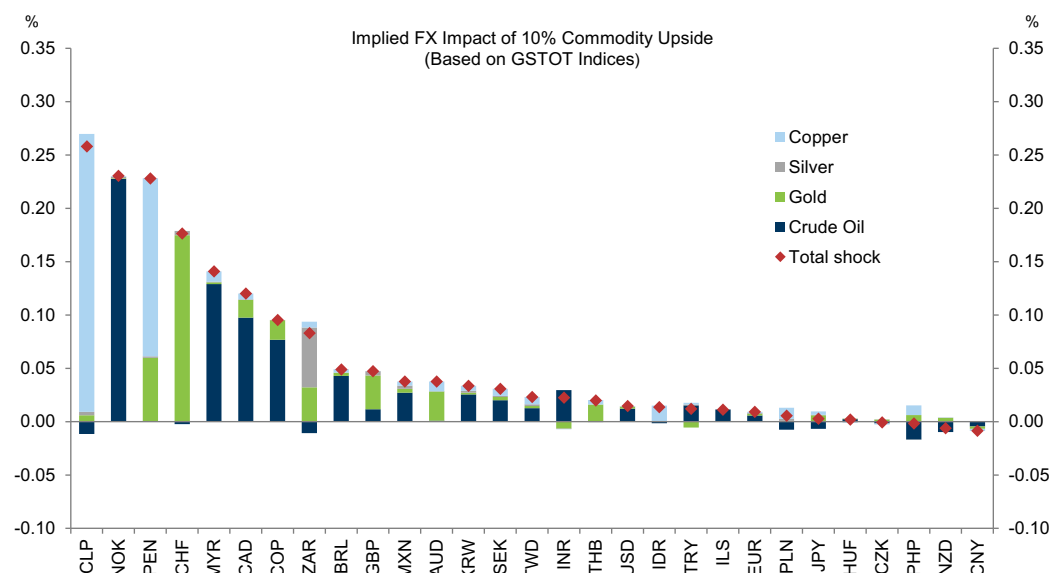

In FX, we expect the negative supply shock and risks to growth to dominate the distributional terms of trade (ToT) effects, at least initially, and particularly after market moves have already reflected some ToT dynamics in recent weeks. In an environment of risk down and oil prices up, the Dollar should still be the haven of choice, second only to the Japanese Yen, while fundamental beneficiaries like NOK tend to only outperform other risky currencies on a relative basis. While the Dollar's observed correlations have shifted somewhat in the last year, it is different when the shocks are global. There are a number of fundamental and technical reasons why the Dollar tends to benefit from global shocks that impair both risk sentiment and the real economy. Many oil exporters are also exposed to global growth, and therefore the risk beta tends to dominate if sentiment deteriorates sharply.

If the commodity effects are durable even after the initial market disruption—which would have some parallels to 2022—the distributional effects can start to reassert themselves in FX, as they have in recent weeks. We use our GSTOT framework to assess the likely FX implications of various commodity price shocks, and 图表 3 shows the relative outperformers implied by a scenario where gold, silver, copper, and oil prices increase by another 10% each.

For oil in particular, our estimates of the implied terms of trade impact and pass-through to FX suggest that NOK, MYR, CAD, and COP should be the biggest beneficiaries. Meanwhile, a rally in gold and other precious metals should benefit CHF as well as PEN and ZAR. The extent of further upside in these currencies may be limited, though, by the outperformance already seen this year off the back of commodity tailwinds and the scope for more severe risk-off that could offset some of

the benefit from higher oil and metals prices. Overall, CHF would tend to see the biggest initial gains due to its safe-haven status and related gold beta. But any sharp appreciation would likely see the SNB intervene in more meaningful size to limit Franc appreciation (as they did at the start of the Russia Ukraine conflict in 2021). ILS may be the bigger mover (in the opposite direction), and it has also been our preferred funder for tech-related volatility. Bank of Israel intervention is also a possibility as the central bank intervened in both October 2023 and June 2025. But current USD/ILS levels are much lower than in those episodes, so we see a relatively higher threshold for intervention.

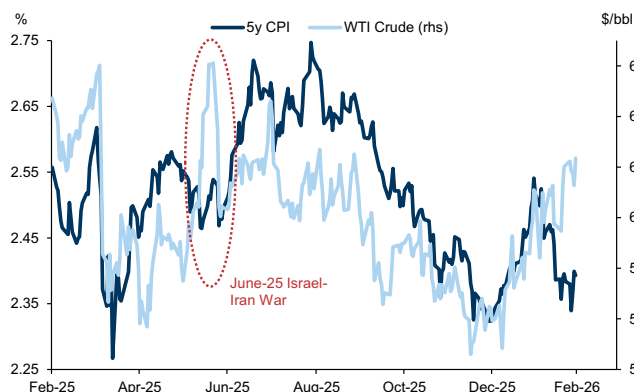

图表 3: Our TOT framework suggests NOK, MYR, CAD, and COP should be the biggest beneficiaries of oil upside, while a precious metal rally should benefit CHF as well as PEN and ZAR

资料来源：高盛全球投资研究部

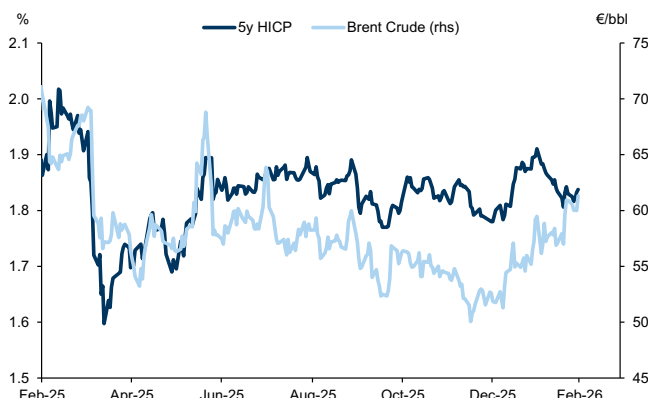

For rates, the tension between inflation upside and growth downside of a negative supply shock will be key to the response. Our prior work on the sensitivity of inflation and real rates to oil prices shows that a 10% boost to oil prices tends to raise 2y breakevens by 15-20bp, with a smaller bullish impact on real rates, corresponding to a 5-10bp impact on 2y nominal rates. But we typically find that supply-driven oil price shocks have a significantly lower beta on traded inflation compared with demand shocks—a result consistent with the relatively muted reaction in US breakevens to the June 2025 jump in oil prices and the recent shifts in the inflation curve that, until late last week, appeared to reflect AI-related worries rather than energy price risks (图表 4). This is likely because supply shocks often prove temporary, and also because of the negative risk reaction associated with supply tightening in energy markets, which drives down growth expectations and thus weighs on other sources of inflation.

图表 4: Last summer's oil price spike and recent upside have had limited impact on traded inflation beyond the very front-end

图表 5: A more muted sensitivity of traded inflation to energy is typical of supply-driven shocks
5y HICP pricing vs oil prices

资料来源：高盛全球投资研究部, Goldman Sachs FICC and Equities

More clear than the directional impact on rate levels, supply shocks tend to exert flattening pressure on the front-end of the curve as inflation constrains the near-term ability to cut while growth risks are more supportive further out. In that sense, we would anticipate the recent US curve dynamics of front-end flattening and 5y outperformance to extend, at least initially. If markets start to price greater risk of a sustained conflict, potential fiscal considerations could be a headwind to the long-end and weigh on swap spreads (or other carry expressions like European sovereign spreads), which may also face pressure from an increase in volatility.

In Europe, we typically find a smaller real rate decline in response to energy price shocks vs the US. And while higher energy prices would represent a negative terms of trade shock for the Euro area as a whole, the source of recent improvement in growth is due less to lower energy prices than to the ramping German fiscal expansion working its way into the real economy. We think this combination presents hawkish risks for the EUR front-end, although in line with the historical relationship this would likely flatten the curve as negative risk sentiment helps anchor longer term yields.

Of course, the magnitude and starting point for the shock matter, with the recent 2022 energy price shock a reminder of conditions where supply shocks risk spillover over into inflation expectations. Underlying inflation dynamics have shifted meaningfully since 2022, but elevated fiscal spending, AI investment and recent rate cuts could still contribute to higher inflation expectations in the scenario of extended cost-push energy inflation. When coupled with the potential for higher business cycle volatility, this makes it harder to gain conviction on directional views on rates over the medium run, and instead points to higher rates volatility. In addition, the return of supply-side volatility at the margin may undermine the case for duration as a portfolio hedge, given it complicates the growth / inflation trade-off. This suggests higher bond risk premium in theory, but unless the oil shock is large and persistent we would expect this effect to be small initially.
